Small Assignment: Nested Structure and Simple Class

Write a C++ program to model a person's detail with address information using structures and a class.

1. **Define a nested structure**
   Create a structure named `Address` containing:
   - `houseNo` (integer)
   - `street` (string)
   - `city` (string)
   - `state` (string)
   - *Inside* `Address`, define another structure called `PIN` with:
     - `code` (integer)
     - `country` (string)
2. **Define a simple class**
   Create a class `Person` with **private** data members:
   - `name` (string)
   - `age` (integer)
   - `addr` (an object of type `Address`)

   Provide **public** member functions:

   - A parameterised constructor to initialise `name`, `age`, and all fields of `addr` (including nested `PIN`).
   - `void display()` — prints all person details including full address and PIN.
3. **Demonstrate in `main()`**
   - Create a `Person` object with sample data.
   - Call `display()` to show the output.

Expected output format (example):

```
Name: Alice
Age: 30
Address: 42, Park Lane, Springfield, Stateland
PIN: 123456, USA
```

This assignment covers:

- **Structure** (`Address`)
- **Nested structure** (`PIN` inside `Address`)
- **Simple class** (`Person`) with encapsulation and a constructor.
